Noninvasive Ventilation, NIPPV, Controlled Mechanical Ventilation (CMV)

ABSTRACT

Noninvasive ventilation (NIV) is the delivery of mechanical ventilation without using on Non invasive artificial airway for the management of acute respiratory failure caused by various etiologies. The aim of this study was to compare the efficacy and resource consumption of Non invasive ventilation against controlled mechanical ventilation (CMV) in patients with respiratory failure this study is conducted to find out role of NIV comparing CMV patients in respiratory failure.

Aim: To assess the role of noninvasive ventilation in respiratory failure patients comparing with control group under controlled mechanical ventilation.

Methods:This prospective observational study conducted on 50 adult patients, divided into two groups of 25 patients each. The control group studied by intubating and connecting to controlled mechanical ventilation and the study group directly by noninvasive ventilation admitted to the medical ICU of Rajah Muthiah Medical college and hospital, Chidambaram. In south India during the period 2016 Jan to 2018 March. Were evaluated for feasibility of NIV patients with respiratory failure were randomized to receive either NIV or endotracheal intubation and CMV.

Results: In our study length of ICU stay in NIV group was less than 5 days, in CMV it was less than 10 days. In CMV group, out of 25 patients, 4 patients undergone for tracheostomy. In NIV group ICU mortality was 2 out of 25 patients and 7 out of 25 in CMV group. Complications were not there in NIV group excepts skin bruises and discomfort due to ill fitting face mask in 4 out of 25 patients. Where as in CMV group complications has occurred mainly ventilator associated pneumonia (3/25) and pneumothorax (2/25).

Conclusion: This study has demonstrated that NIPPV is not only a feasible ventilator modality in developing countries but also a treatment that is associated with significant improvements in physiological and clinical outcomes. The application of NIV resulted in low rate of endotracheal Intubation, fewer complications and was well tolerated in our patients lower intial cost of Invasive ventilators, reduced duration of hospitalization and complication rates are likely to translate to favorable economic benefits.

INTRODUCTION

Non Invasive ventilation (NIV) is the delivery of mechanical ventilation without using an Invasive artificial airway for the management of acute respiratory failure caused by various etiologies. The aim was to compare the efficacy and resource consumption of non invasive ventilation against controlled mechanical ventilation (CMV) in patients with respiratory failure (1.2).

Additional benefits of lesser need for sedation and a decrease in the risk of airway damage or pneumonia⁽³⁾. Non invasive ventilation can reduce the frequency of breathing, augument tidal volume, improve gas exchange and rest the muscles of respirations. Many patients with severe respiratory failure, impaired sensorium, haemodynamic instability or difficulty clearing secretions, however undergo direct intubation or intubation after a failed attempt at non-invasive ventilation.

Endotracheal Intubation and Non invasive mechanical ventilation, though life seving in critical care settings, are related to complications that may prolong hospital stay and increase nosocomial pneumonia (2) 1% per day continous mechanical ventilation may be responsible for generalized myopathy.

MATERIALS AND METHODS

This prospective observational study conducted on 50 adult patients divided into two groups 25 patients each. The control group studied by Intubating and connecting to controlled mechanical ventilation and the study group directly by Invasive ventilation admitted to the medical ICU of Rajah Muthiah medical college and Hospital, Chidambaram in south India during the period 2016 to 2018 march were evaluated for feasibility for NIV patients with respiratory failure were randomized to receive either NIV or Endotracheal intubation

and CMV. The efficacy of non invasive ventilation analyzed by comparing with control group taking into consideration of the length of ICU stay and time taken for full recording. Patients excluded are Terminally moribund patients, Associated valvular heart diseases, and acute ventricular failure. Parameters like Arterial blood gas, chest Xray-AP, ECG, Serum Electrolytes. Monitored with continous cardiac, pulseoximetry, Temperature monitoring and ventilator parameters.

Patients were eligible for entry to the study if they presented with respiratory failure without a clinically perceived need for immediate life saving endotracheal intubation. On Intiation of NIV, continous application was encouraged supplemental oxygen therapy was administered with NIV and titrated to achieve a saturation of 88-92% unless clinically determined otherwise. Oximetry was correlated with arterial blood gas analysis at the end of 1 hr of application of NIV and at subsequent intervals determined by the treating physician. Previous studies have suggested that clinical and oximetric improvements at 1 h protend a favorable, response ^(4,5). If there is deterioration at the end of 1 hr endotracheal intubation was considered.

The primary outcome measure in this study was the need for endotracheal intubation due to early NIPPV failure (i.e. lack of response after 1 h of treatment). Secondary outcomes included changes in arterial blood gas (ABG) parameters, hospital mortality, duration of ICU and hospital stay and complications. Some complications include gastric distention aspiration pneumonia hypotension and pneumothorax⁽⁶⁾. The control group intubated and connected to mechanical ventilator. Assist control ventilation was applied in 25 patients admitted in ICU sedation was administered in all patients. The 2 hr weaning of spontaneous breathing with additional O2 and air humidification within 24 hrs. The three criteria met are minute volume 10L/min, VC 10ml/kg, VT.5ml/kg, f<35/min, F/VT<105 cycles /min/L and SaO2 90% for an FIO2 of 40%. In case satisfied patients were extubated and given nasal oxygen.

RESULTS

A total of 300 patients admitted to the medical ICU during the period 2016 to 2018 march were evaluated for feasibility of NIPPV

| Length of stay in | P- Value | | |
|-------------------|----------|-----------|--|
| NIV | CMV | r - value | |
| 2+2 | 7+3 | 0.001 (S) | |

25 patients were assigned to NIV and 25 were assigned to CMV.

Failure rates in the hyperbaric respiratory failure group were 2/25 and the hypoxemic respiratory failure group 2/25. The Success rate with NIV was 85% with 21 patients weaned successfully off non invasive ventilation. In the group assigned to NIV, 4 patients were intubated vs 25 patients in the group intubated who were assigned to CMV. The length of stay in the NIV were less than 4 days and less than 10 days in CMV.

DISCUSSION

In these studies, NIV was associated with are reduced need for invasive ventilation, decreased mortality and shorter length off hospital stay. It's found that NIV avoids intubation in almost 50% of patient with respiratory failure who need mechanical ventilation. The result also suggest that NIV might be associated with lower morality similar studies showed both NIV and CMV significantly improved gas exchange, long duration ICU stay for mechanical ventilated vs short duration of ICU stay for NIV patient. But in our study length & ICU stay in NIV group was less than 5 days, in CMV in was less than 10 days. In NIV group ICU mortality was 2 out of 25 patients and 7 out of 25 in CMV group.
